ABSTRACT

Grap is a language for describing plots of data. This graph of the 1984 age distribution in the United States
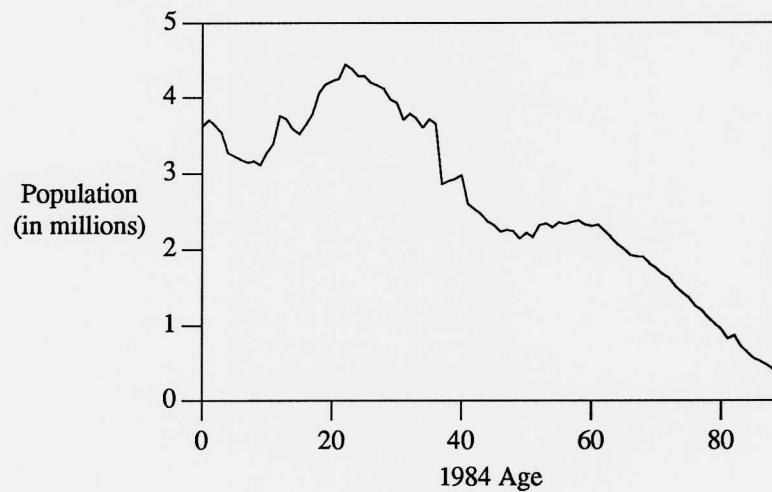

is produced by the *grap* commands

```
coord x 0,89 y 0,5
label left "Population" "(in millions)"
label bottom "1984 Age"
draw solid
copy "agepop.d"
```

(Each line in the data file `agepop.d` contains an age and the number of Americans of that age alive in 1984; the file is sorted by age.)

The *grap* preprocessor works with *pic* [4] and *troff* [5]. Most of its input is passed through untouched, but statements between `.G1` and `.G2` are translated into *pic* commands that draw graphs.

Revised, May 1991

Grap — A Language for Typesetting Graphs
Tutorial and User Manual

1. Introduction

Grap is a language for describing graphical displays of data. It provides such services as automatic scaling and labeling of axes, and `for` statements, `if` statements, and macros to facilitate user programmability. *Grap* is intended primarily for including graphs in documents prepared on the UNIX® operating system, and is only marginally useful for elementary tasks in data analysis.

Section 2 of this document is a tutorial introduction to *grap*; readers who find it slow going may wish to skim ahead. The examples in Section 3 illustrate the various kinds of graphs that *grap* can produce and some common *grap* idioms. Mundane matters about using *grap* are discussed in Section 4, and Section 5 contains a brief reference manual.

We have tried to illustrate good principles of statistics and graphical design in the graphs we present. In several places, though, good taste has lost to the necessity of illustrating *grap* capabilities. Readers interested in statistical integrity and taste should consult the literature, for example [2], [6], [3].

## 2. Tutorial

The following is a simple *grap* program†

```
.G1
54.2
49.4
49.2
50.0
48.2
...
43.87
.G2
```

The single number on each line is the winning time in seconds for the men's 400 meter run, from the first modern Olympic Games (1896) to the twenty-first (1988). If the file `olymp.g` contains the text above, then typing the command

```
grap olymp.g | pic | troff > junk
```

creates a *troff* output file `junk` that contains the picture

---

† Throughout this document we will show only the first five lines and the last line of data files; omitted lines are indicated by "...".
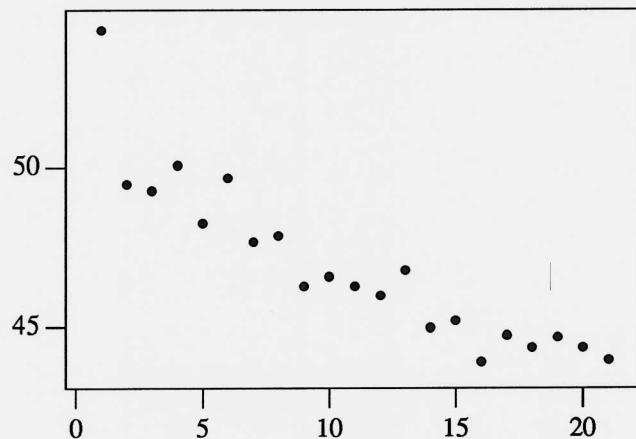

The graph shows the decrease in winning times from 54.2 seconds to 43.87 seconds. If the times are contained in the file 400mtimes.d, we could produce the same graph with the shorter program

```
copy "400mtimes.d"
```

Writing copy fname"" in a *grap* program is equivalent to including the contents of file fname at that point in the file. (In the interests of compatibility with other programs, include is a synonym for copy.)

Each line in the file 400mpairs.d contains two numbers, the year of the Olympics and the winning time:

```
1896 54.2
1900 49.4
1904 49.2
1908 50.0
1912 48.2
...
1988 43.87
```

If we plot this data with the program

```
copy "400mpairs.d"
```

the bottom (x) axis represents the year of the Olympics.
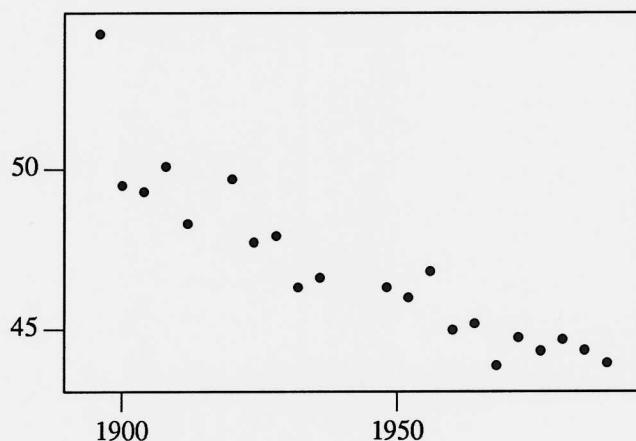

The "holes" in x-values reflect the fact that the 1916, 1940, and 1944 Olympics were cancelled due to war. Because the previous data (in 400mtimes.d) had just one number per line, *grap* viewed it as a "time series" and supplied x-values of 1, 2, 3, $\cdots$ before plotting the data as y-values. The input to the second program has two values per line, so they are interpreted as (x,y) pairs.

Rather than a scatter plot of points, we might prefer to see the winning times connected by a solid line. The program

```
draw solid
copy "400mpairs.d"
```

produces the graph
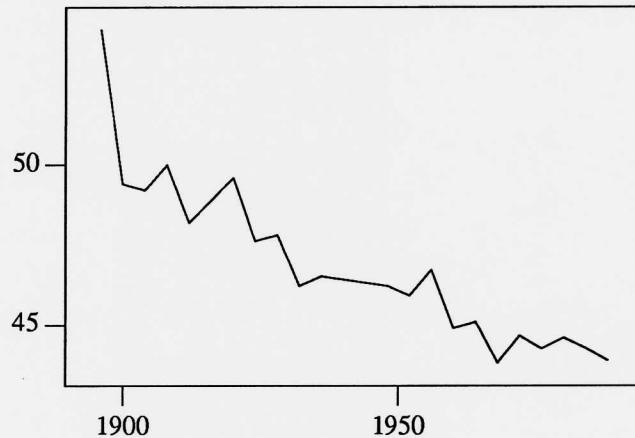

Eric Liddell of Great Britain won his gold medal in Paris in 1924 with a time of 47.6 seconds. (Remember ''Chariots of Fire''?)

We can make the graph more attractive by modifying its frame and adding labels.

```
frame invis ht 2 wid 3 left solid bot solid
label left "Time" "(in seconds)"
label bot "Olympic 400 Meter Run: Winning Times"
draw solid
copy "400mpairs.d"
```

The `frame` command describes the graph's bounding box: the overall frame (which has four sides) is invisible, it is 2 inches high and 3 inches wide (which happen to be the default height and width), and the left and bottom sides are solid (they could have been dashed or dotted instead). The labels appear on the left and bottom, as requested.

Olympic 400 Meter Run: Winning Times
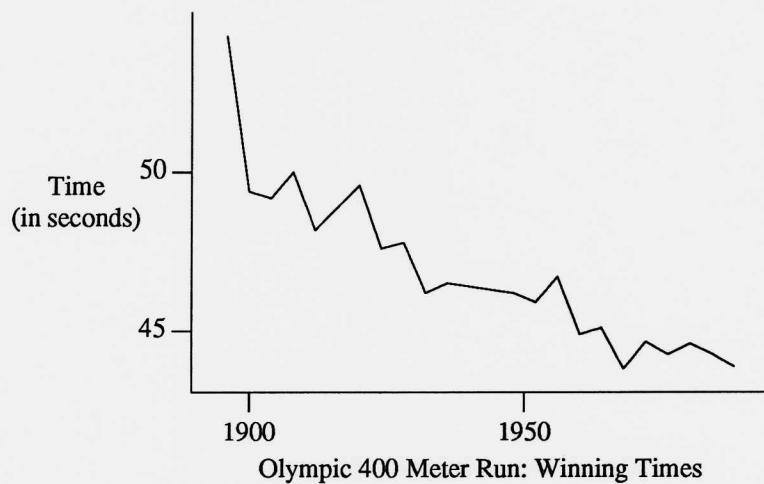

To set the range of each axis, *grap* examines the data and pads both dimensions by seven percent at each end. The `coord` (''coordinates'') command allows you to specify the range of one or both axes explicitly; it also turns off automatic padding.

```
frame invis ht 2 wid 3 left solid bot solid
label left "Time" "(in seconds)"
label bot "Olympic 400 Meter Run: Winning Times"
coord x 1894,1990 y 42,56
draw solid
copy "400mpairs.d"
```

The *y*-axis now ranges from 42 to 56 seconds (a little more than before), and the *x*-axis from 1894 to 1990 (a little less).

Olympic 400 Meter Run: Winning Times
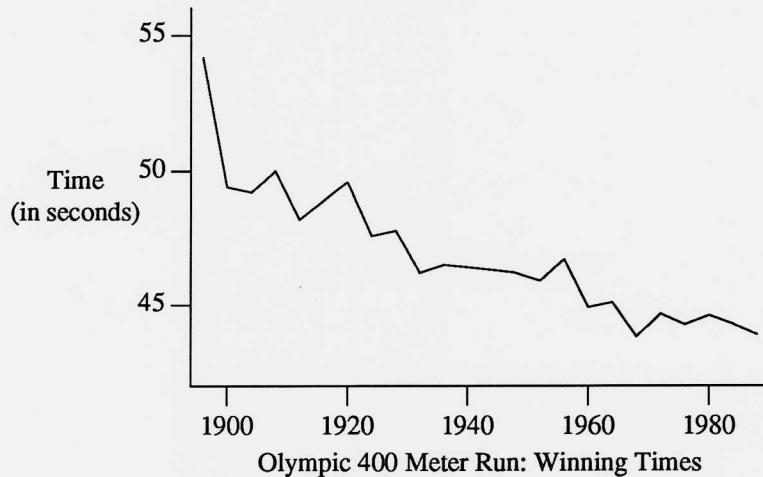

The ticks in the preceding graphs were generated by *grap* guessing at reasonable values. If you would rather provide your own, you may use the `ticks` command, which comes in the flavors illustrated below.

```
frame invis ht 2 wid 3 left solid bot solid
label left "Time" "(in seconds)" left .2
label bot "Olympic 400 Meter Run: Winning Times"
coord x 1894,1990 y 42, 56
ticks left out at 44 "44", 46, 48 "48", 50, 52 "52", 54
ticks bot in from 1900 to 1980 by 20
draw solid
copy "400mpairs.d"
```

The first `ticks` command deals with the left axis: it puts the ticks facing out at the numbers in the list. *Grap* puts labels only at values with strings, except that when no labels at all are given, each number serves as its own label, as in the second `ticks` command. That command is for the bottom axis: it puts the ticks facing in at steps of 20 from 1900 to 1980. The command `ticks off` turns off all ticks. *Grap* does its best to place labels appropriately, but it sometimes needs your help: the `left .2` clause moves the left label 0.2 inches further left to avoid the new ticks.

Olympic 400 Meter Run: Winning Times
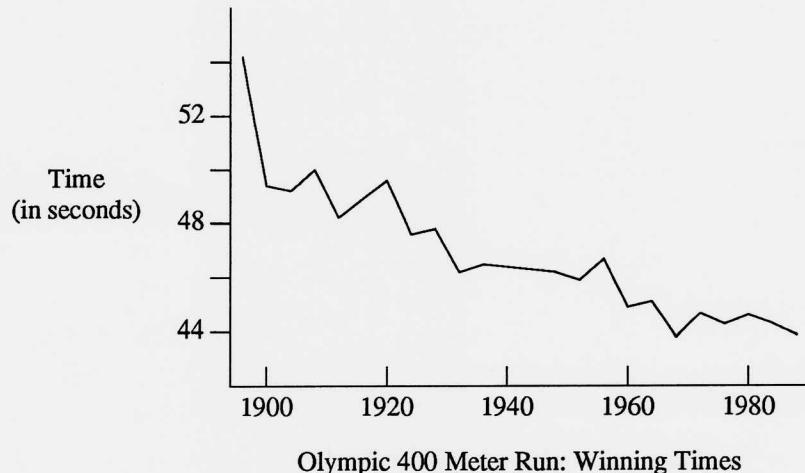

The file `400wpairs.d` contains the times for the women's 400 meter race, which has been run only since 1964.

```
1964 52
1968 52
1972 51.08
1976 49.29
1980 48.88
...
1988 48.65
```

To add these times to the graph, we use

```
frame invis ht 2 wid 3 left solid bot solid
label left "Time" "(in seconds)" left .2
label bot "Olympic 400 Meter Run: Winning Times"
coord x 1894,1990 y 42, 56
ticks left out at 44 "44", 46, 48 "48", 50, 52 "52", 54
ticks bot in from 1900 to 1980 by 20
draw solid
copy "400mpairs.d"
new dotted
copy "400wpairs.d"
"Women" size -3 at 1958,52
"Men" size -3 at 1910,47
```

The `new` command tells *grap* to end the old curve and to start a new curve (which in this case will be drawn with a dotted line). Text is placed on the graph by commands of the form

```
"string" at xvalue, yvalue
```

The `size` clauses following the quoted strings tell *grap* to shrink the characters by three points (absolute point sizes may also be specified). Strings are usually centered at the specified position, but can be adjusted by clauses to be illustrated shortly.

Olympic 400 Meter Run: Winning Times
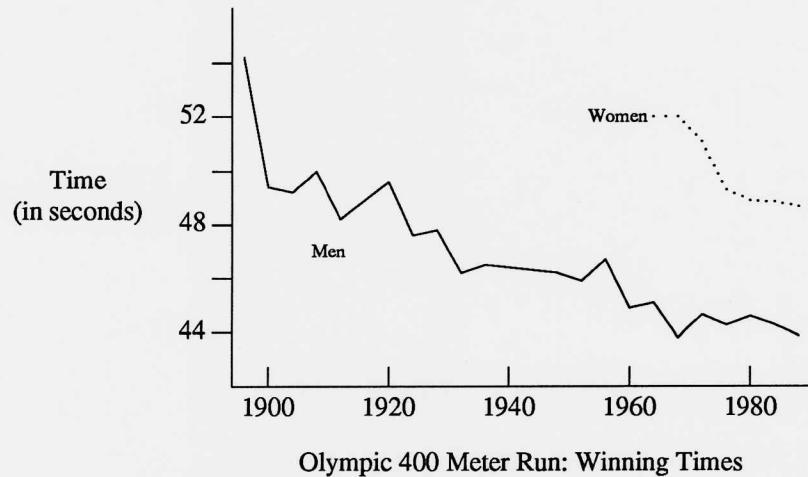

The file `phone.d` records the number of telephones in the United States from 1900 to 1970.

```
00 1.3
01 1.8
02 2.3
03 2.8
04 3.3
...
70 120.2
```

Each line gives a year and the number of telephones present in that year (in millions, truncated to the nearest hundred thousand). The simple *grap* program

```
copy "phone.d"
```

produces the simple graph
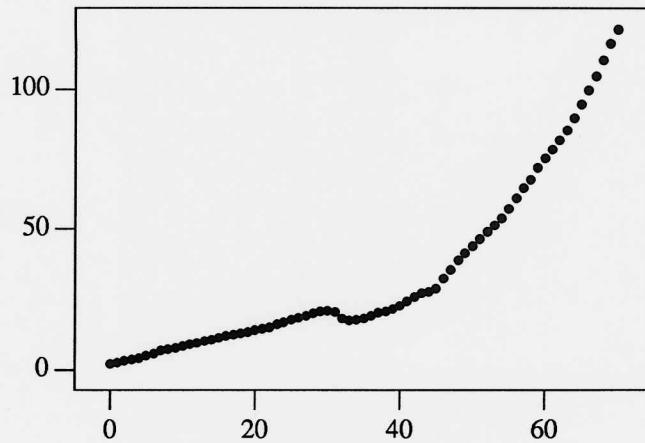

The number of telephones appears to grow exponentially; to study that we will plot the data with a logarithmic *y*-axis by adding `log y` to the `coord` command. We will also add cosmetic changes of labels, more ticks, and a solid line to replace the unconnected dots.

```
label left "Millions of" "Telephones" "(log scale)" left .5
coord x 0,70 y 1,130 log y
ticks left out at 1, 2, 5, 10, 20, 50, 100
ticks bot out at 0 "1900", 70 "1970"
ticks bot out from 10 to 60 by 10 "'%g"
draw solid
copy "phone.d"
```

The third `ticks` command provides a string that is used to print the tick labels. C programmers will recognize it as a `printf` format string; others may view the `%g` as the place to put the number and anything else (in this case just an apostrophe) as literal text to appear in the labels. To suppress labels, use the empty format string (`""`). The program produces
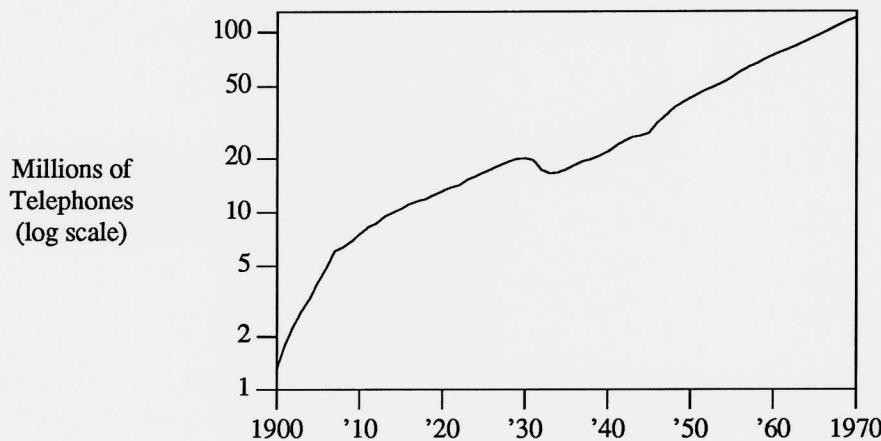

The number of telephones grew rapidly in the first decade of this century, and then settled down to an exponential growth rate upset only by a decrease in the Great Depression and a post-war growth spurt to return the curve to its pre-Depression line.

Our presentation so far has been to start with a simple *grap* program that illustrates the data, and then refine it. Later in this document we will ignore the design phase, and present rather complex graphs in their final form. Beware.

All the examples so far have placed data on the graph implicitly by copying a file of numbers (either a time series with one number per line or pairs of numbers). It is also possible to draw points and lines explicitly. The *grap* commands to draw on a graph are illustrated in the following fragment.

```
frame ht 2 wid 2
coord x 0,100 y 0,100
grid dotted bot from 20 to 80 by 20
grid dotted left from 20 to 80 by 20

"Text above"   above at 50,50
"Text rjust  " rjust at 50,50
bullet at 80,90
vtick  at 80,80
box    at (80,70)
times  at 80, 60

circle at 50,50
circle at 50,80 radius .25
line dashed from 10,90 to 30,90
arrow from 10,70 to 30,90

draw A solid
draw B dashed delta
next A at 10,10
next B at 10,20
next A at 50,20
next A at 90,10
next B at 50,30
next B at 90,30
```

The `grid` command is similar to the `ticks` command, except that grid lines extend across the frame. The next few commands plot text at specified positions. The plotting characters (such as `bullet`) are implemented as predefined macros — more on that shortly. Unlike arbitrary characters, the visual centers of the markers are near their plotting centers. The `circle` command draws a circle centered at the specified location. A radius in inches may be specified; if no radius is given, then the circle will be the small circle shown at the center of the graph. The `line` and `arrow` commands draw the obvious objects shown at the upper left.
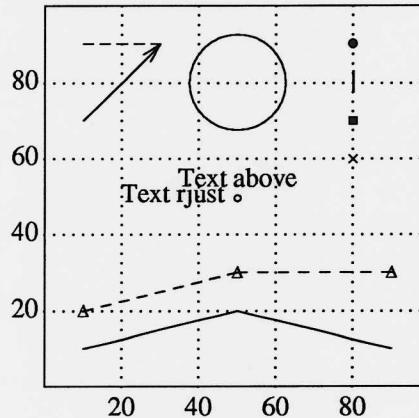

This figure also illustrates the combined use of the `draw` and `next` commands. Saying `draw A solid` defines the style for a connected sequence of line fragments to be called A. Subsequent commands of `next A at` *point* add *point* to the end of A. There are two such sequences active in the above example (A and B); note that their `next` commands are intermixed. Because the predefined string `delta` follows the specification of B, that string is plotted at each point in the sequence.

Grap has numeric variables (implemented as double-precision floating point numbers) and the usual collection of arithmetic operators and mathematical functions; see the reference section for details.

Grap provides the same rudimentary macro facility that *pic* does:

```
define name   { replacement text }
```

defines *name* to be the *replacement text*. The replacement may be any text that contains balanced open and closing braces { }. (Alternatively, the *replacement text* may be quoted by any single character that does not appear in the replacement; the string is terminated by the next occurrence of that character.) Any subsequent occurrence of *name* will be replaced by *replacement text*.

The replacement text of a macro definition may contain occurrences of $1, $2, etc.; these will be replaced by the corresponding actual arguments when the macro is invoked. The invocation for a macro with arguments is

```
name(arg1, arg2, ...)
```

Non-existent arguments are replaced by null strings.

The following *grap* program uses macros and arithmetic to plot crude approximations to the square and square root functions.

```
frame ht 1.5 wid 1.5
define square { ($1)*($1) }
define root { ($1^0.5) }
define P {
        times at i, square(i); i = i+1
        circle at j, root(j); j = j+5
}
i = 1; j = 5
P; P; P; P; P
```

The macro `root` uses the ^ exponentiation operator. (Because *grap* has the square root function `sqrt`, that macro is in fact superfluous.) The program produces
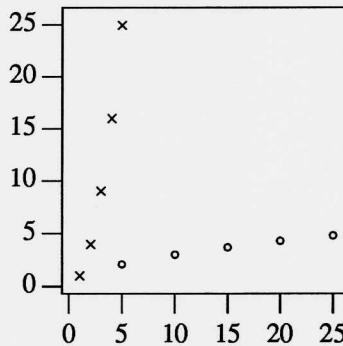

The `copy` command has a `thru` parameter that allows each line of a file to be treated as though it were a macro call, with the first field serving as the first argument, and so on. This is the typical *grap* mechanism for plotting files that are not stored as time series or as (x,y) pairs. We will illustrate its use on the file `states.d`, which contains data on the fifty states.

```
AK      1       401851
WY      1       469557
VT      1       511456
DE      1       594338
ND      1       652717
...
CA      45      23667902
```

The first field is the postal abbreviation of the state's name (Alaska, Wyoming, Vermont, ...), the second field is the number of Representatives to Congress from the state after the 1981 reapportionment, and the third field is the population of the state as measured in the 1980 Census. The states appear in increasing order of population.

We will first plot this data as population, representative pairs. (In the `coord` statement, `log log` is a synonym for `log x log y`.)

```
label left "Representatives" "to Congress" left .3
label bot "Population (Millions)"
coord x .3,30 y .8,50 log log
define PlotState { circle at ($3/1e6,$2) }
copy "states.d" thru PlotState
```

Although the population is given in persons, the `PlotState` macro plots the population in millions by dividing the third input field by one million (written in exponential notation as `1e6`, for 1×10^6).

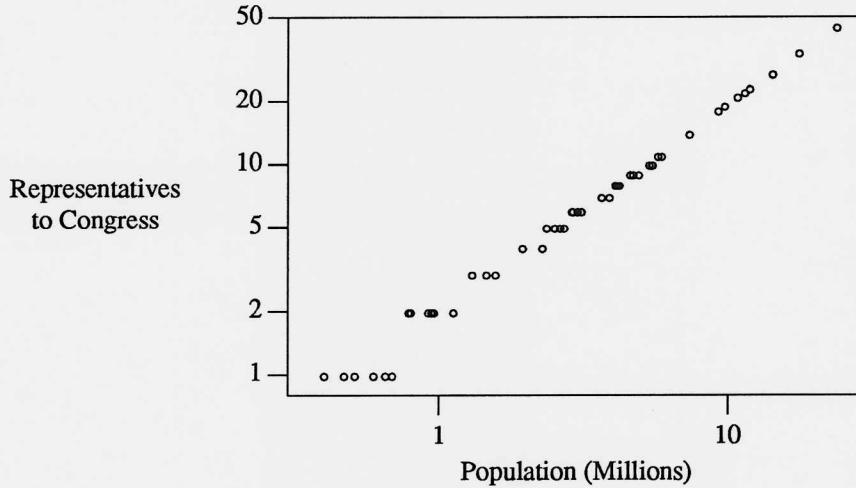

Using `circle` as a plotting symbol displays overlapping points that are obscured when the data is plotted with bullets. The representation of a state is roughly proportional to its population, except in the very small states.

Our next plot will use the state's rank in population as the *x*-coordinate and two different *y*-coordinates: population and number of representatives. We will use two `coord` commands to define the two coordinate systems `pop` and `rep`. We then explicitly give the coordinate system whenever we refer to a point, both in constructing axes and plotting data.

```
frame ht 3 wid 3.5
label left "Population" "in Millions" "(Plotted as \(bu)"
label bot "Rank In Population" up .2
label right "Representatives" "(Plotted as \(sq)"
coord pop x 0,51 y .2,30 log y
coord rep x 0,51 y .3,100 log y
ticks left out at pop .3, 1, 3, 10, 30
ticks bot out at pop 1, 50
ticks right out at rep 1, 3, 10, 30, 100
thisrank = 50
copy "states.d" thru {
        bullet at pop thisrank,$3/1e6
        square at rep thisrank,$2
        thisrank = thisrank - 1
}
```

The `copy` statement in the program uses an *immediate macro* enclosed in curly brackets and thus avoids having to name a macro for this task. Because the program assumes that the states are sorted in increasing order of population, it generates `thisrank` internally as a *grap* variable. The program produces
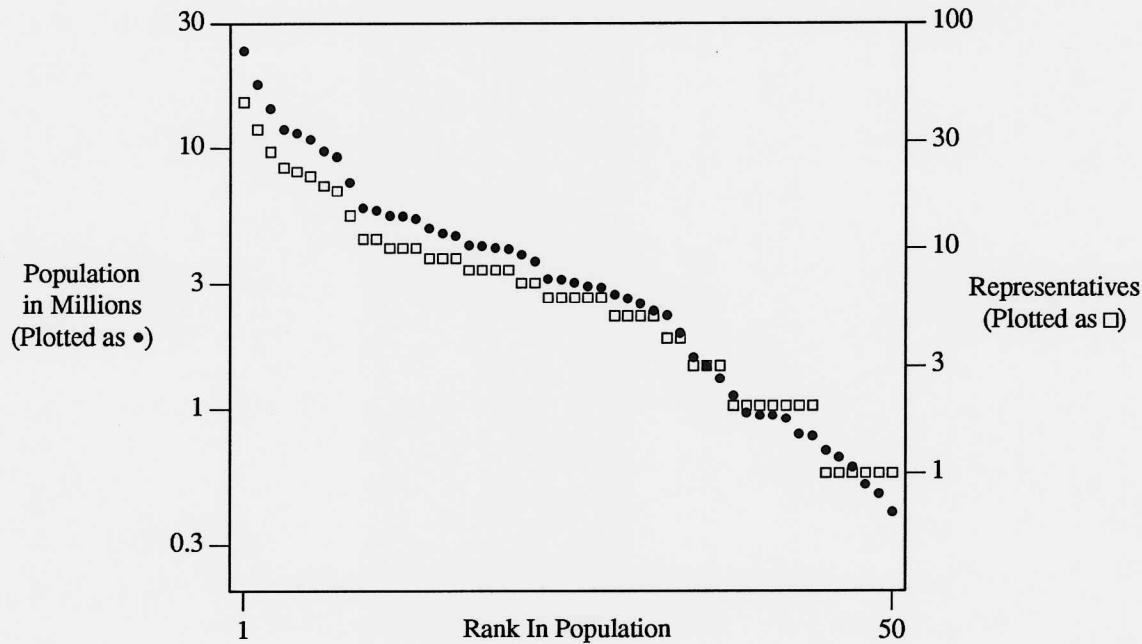

The plotting symbols were chosen for contrast in both shape and shading. This graph also indicates that representation is proportional to population. Once we see this graph, though, we should realize that we don't really need two coordinate systems: we can relate the two by dividing the population of the U.S. — about 226,000,000 — by the number of representatives — 435 — to see that each representative should count as 520,000 people. If the purpose of this graph were to tell a story about American politics rather than to illustrate multiple coordinate systems, it should be redrawn with a single coordinate system.

Many graphs plot both observed data and a function that (theoretically) describes the data. There are many ways to draw a function in *grap*: a series of `next` commands is tedious but works, as does writing a simple program to write a data file that is subsequently read and plotted by *grap*. The `for` statement often provides a better solution. This *grap* program

```
frame ht 1 wid 3
draw solid
pi = atan2(0,-1)
for i from 0 to 2*pi by .1 do { next at i, sin(i) }
```

produces
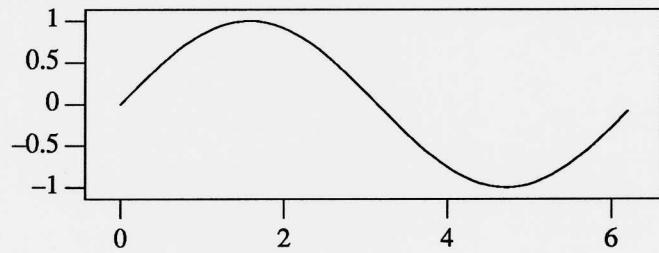

The `for` statement uses the same syntax as the `ticks` statement, but the `from` keyword can be replaced by "=", which will look more familiar to programmers. It varies the index variable over the specified range and for each value executes all statements inside the delimiter characters, which use the same rules as macro delimiters. It is, of course, useful for many tasks beyond plotting functions.

The `if` statement provides a simple mechanism for conditional execution. If a file contains data on both cities and states (and lines describing states have "S" in the first field), it could be plotted by statements like

```
if "$1" == "S" then {
        PlotState($2,$3,$4)
} else {
        PlotCity($2,$3,$4,$5,$6)
}
```

The `else` clause is optional; delimiters use the same rules as macros and `for` statements.

3. A Collection of Examples

The previous section covered the *grap* commands that are used in common graphs. In this section we'll spend less time on language features, and survey a wider variety of graphs. These examples are intended more for browsing and reference than for straight-through reading. Be prepared to refer to the manual in Section 5 when you stumble over a new *grap* feature.

The file `cars.d` contains the mileage (miles per gallon) and the weight (pounds) for 74 models of automobiles sold in the United States in the 1979 model year.

```
22   2930
17   3350
22   2640
17   2830
23   2070
...
17   3170
```

The trivial *grap* program

```
copy "cars.d"
```

produces
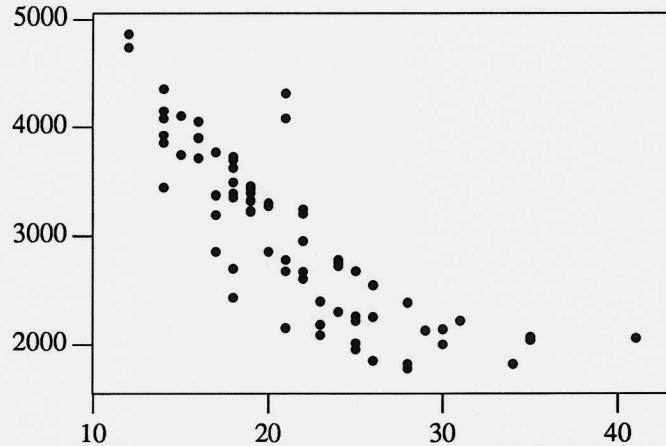

This graph shows that weights bottom out somewhat below 2000 pounds and that heavier cars get worse mileage; it is hard to say much more about the relationship between weight and mileage.

The next graph provides labels, uses circles to expose data hidden in the clouds of bullets, and re-expresses the *x*-axis in gallons per mile. It also changes the point size and vertical spacing to a size appropriate for camera-ready journal articles and books; the size changes should be made outside the *grap* program. The `.ft` command changes to a Helvetica font, which some people prefer for graphs.

```
.ft H
.ps -2
.vs -2
frame ht 2.5 wid 2.5
label left "Weight" "(Pounds)" left .3
label bot "Gallons per Mile"
coord x 0,.10 y 0,5000
ticks left from 0 to 5000 by 1000
ticks bot from 0 to .10 by .02
copy "cars.d" thru { circle at 1/$1, $2 }
.vs +2
.ps +2
.ft
```

Grap supports logarithmic re-expression of data with the `log` clause in the `coord` statement; any other re-expression of data must be done with *grap* arithmetic, as above.
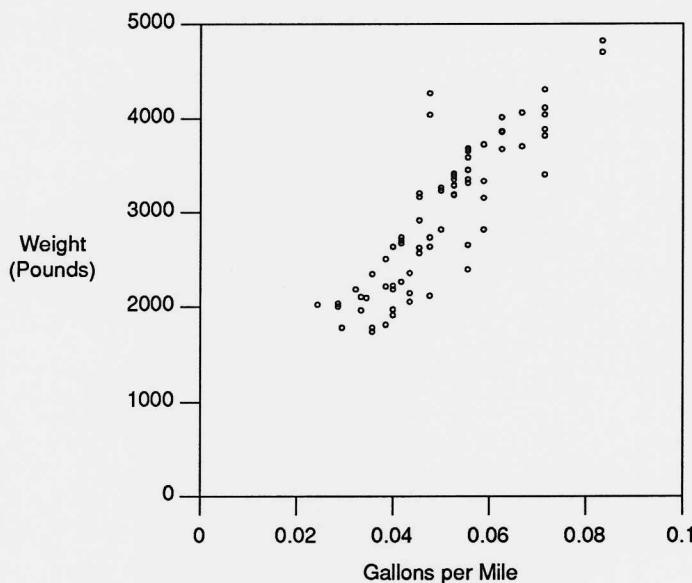

This graph shows that gallons per mile is roughly proportional to weight. (The two outliers near 4000 pounds are the Cadillac Seville and the Oldsmobile 98.)

In *Visual Display of Quantitative Information*, Tufte proposes the "dot-dash-plot" as a means for maximizing data ink (showing the two-dimensional distribution and the two one-dimensional marginal distributions) while minimizing what he calls "chart junk" — ink wasted on borders and non-data labels. His preference is easy to express in *grap*:

```
frame invis ht 3 wid 3
coord x 0, .10 y 0, 5000
copy "cars.d" thru {
        tx = 1/$1; ty = $2
        bullet at tx,ty
        tick bot at tx ""
        tick left at ty ""
}
```

Although visually attractive, we do not find the resulting graph as useful for interpreting the data.

Tufte's graph does point out two facts that are not obvious in the previous graphs: there is a gap in car weights near 3000 pounds (exhibited by the hole in the *y*-axis ticks), and the gallons per mile axis is regularly structured (the ticks are the reciprocals of an almost dense sequence of integers). The reader may decide whether those insights are worth the decrease in clarity.

Throughout the twentieth century, horses, cars and people have gotten faster; let's study those improvements. For horses, we'll consider the winning times of the Kentucky Derby from 1909 to 1988, in the file `speedhorse.d`:

```
126.2
126.4
125.0
129.4
124.8
...
122.2
```

The program

```
label left "Winning Time" "(seconds)" left .3
label bot "Kentucky Derby, 1909 to 1988"
bestsofar = 1000  # Greater than first time
year = 09
copy "speedhorse.d" thru {
        bullet at year, $1
        bestsofar = min(bestsofar, $1)
        line from year, bestsofar to year+1, bestsofar
        year = year+1
}
```

produces the graph

Kentucky Derby, 1909 to 1988
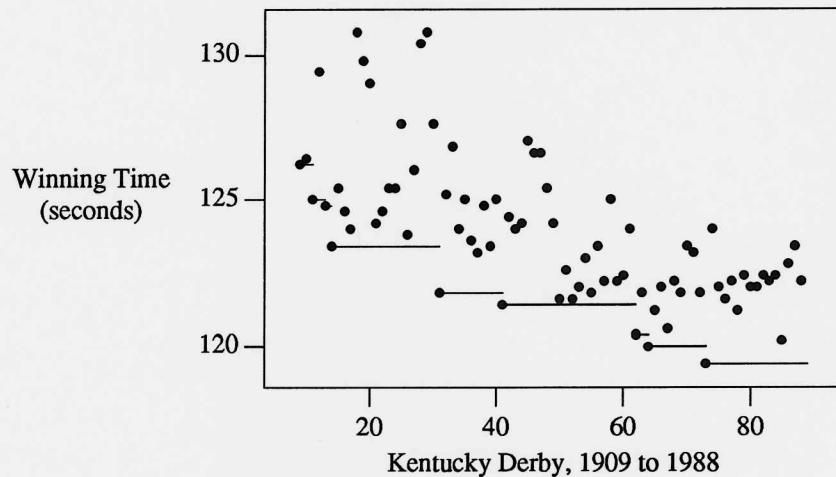

Each race is recorded with a bullet and record times are marked by horizontal lines. Secretariat is the only horse to have run the one-and-a-quarter-mile race in under two minutes; he won in 1973 in 1:59.4.

For automobiles we will study the world land speed record (even though those vehicles are by now just low-flying airplanes). The file speedcar.d lists years in which speed records were set and the record set in that year, in miles per hour averaged over a one-mile course.

```
06      127
10      131
11      141
19      149
20      155
...
83      633
```

We will plot the data with the following *grap* program, which uses nested braces in the copy and if statements.

```
label bot "World Land Speed Record"
label left "Miles" "per" "Hour" left .4
ticks bot out from 10 to 70 by 10 ""
ticks bot out at 0 "1900", 40 "1940", 80 "1980"
firstrecord = 1
copy "speedcar.d" thru {
        if firstrecord == 1 then {
                firstrecord = 0
        } else {
                line from lastyear, lastrec to $1, lastrec
        }
        lastyear = $1; lastrec = $2
}
line from lastyear, lastrec to 84, lastrec
```

Each record line is drawn after the *next* record is read, because the program must know when the record was broken to draw its line. The if statement handles the first record, and the extra line command extends the last record out to the current date.

World Land Speed Record
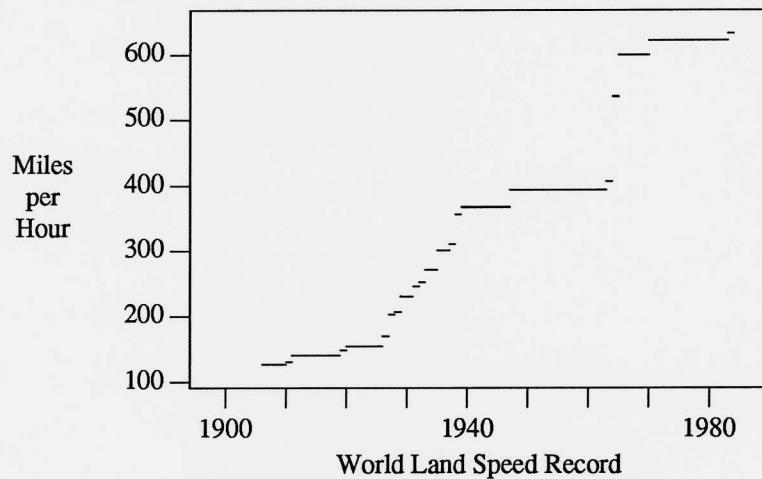

The horizontal lines reflect the nature of world records: they last until they are broken. The records could also have been plotted by a scatterplot in which each point represents the setting of a record, but it would be misleading to connect adjacent points with line segments (which we inappropriately did in the graphs of the Olympic 400 meter run).

The following graph shows the world record times for the one mile run; because its *grap* program is so similar to its automotive counterpart, we won't show the program or data.

World Record One Mile Run
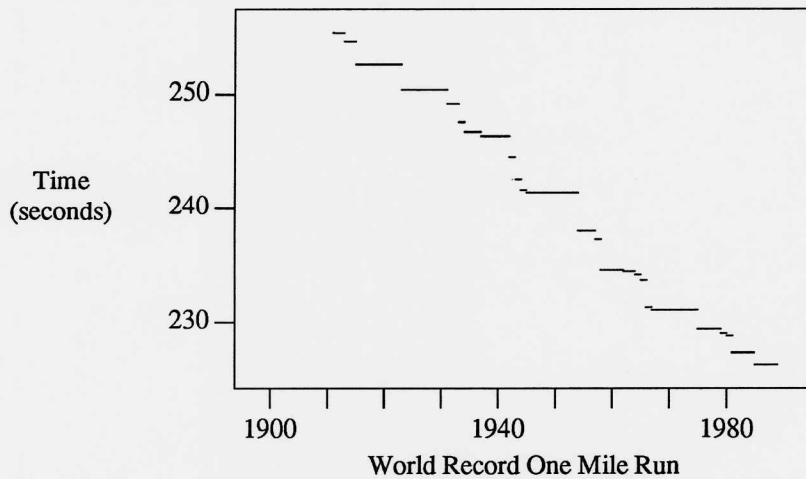

The three graphs show three different kinds of changes. Although horses are getting faster, they appear to be approaching a barrier near two minutes. Cars show great jumps as new technologies are introduced followed by a plateau as limits of the technology are reached. Milers have shown a fairly consistent linear improvement over this century, but there must be an asymptote down there somewhere.

The next file gives the median heights of boys in the United States aged 2 to 18, together with the fifth and ninety-fifth percentiles.

```
 2   82.5   86.8   94.4
 3   89.0   94.9  102.0
 4   95.8  102.9  109.9
 5  102.0  109.9  117.0
 6  107.7  116.1  123.5
 . . .
18  165.7  176.8  187.6
```

The heights are given in centimeters (1 foot = 30.48 centimeters). The trivial program

```
copy "boyhts.d"
```

displays the data as
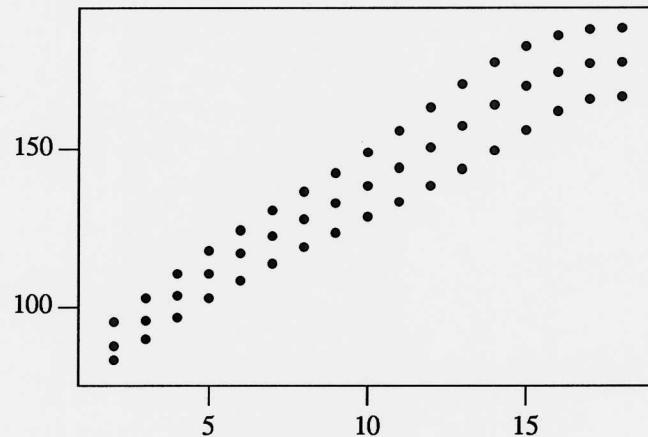

Because there are four numbers on each input line, the first is taken as an x-value and the remaining three are plotted as y-values.

The three curves appear to be roughly straight (at least up to age 16), so it makes sense to fit a line through them. We will use the standard least squares regression in which

$$slope = \frac{n\Sigma xy - \Sigma x\Sigma y}{n\Sigma x^2 - (\Sigma x)^2}$$

(where the summations range over all n x and y values in the data set) and the y-intercept is

$$\frac{\Sigma y - slope\times\Sigma x}{n}$$

The following *grap* program boldly (and rather foolishly) implements that formula.

```
label left "Heights in Feet" "(Median and" "fifth percentiles)"
label bot "Heights of Boys in U.S., ages 2 to 18"
cmpft = 30.48  # Centimeters per foot
minx = 1e12; maxx = -1e12
n = sigx = sigx2 = sigy = sigxy = 0
copy "boyhts.d" thru {
        line from $1, $2/cmpft to $1, $4/cmpft
        ty = $3/cmpft
        bullet at $1,ty
        n = n+1
        sigx = sigx+$1; sigx2 = sigx2+$1*$1
        sigy = sigy+ty; sigxy = sigxy+$1*ty
        minx = min(minx,$1); maxx = max(maxx,$1)
}
# Calculate least squares fit and draw it
slope = (n*sigxy - sigx*sigy) / (n*sigx2 - sigx*sigx)
inter = (sigy - slope*sigx) / n
line from minx, slope*minx+inter to maxx, slope*maxx+inter
```

It plots the extreme fifth percentiles as a bar through the median, which is plotted as a bullet. All heights are converted to feet before plotting and calculating the regression line.

Heights in Feet
(Median and
fifth percentiles)

Heights of Boys in U.S., ages 2 to 18
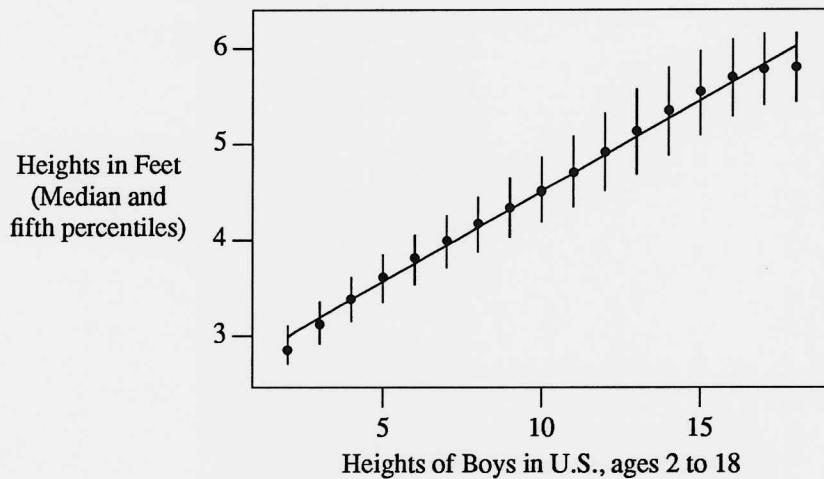

Grap `print` statements write on `stderr` as they are processed by *grap*; their single argument can be either an expression or a string. The `print` statements (which are commented out in the above *grap* program) at one time showed that the regression line is

<div align="center">Height in Feet = 2.61 + .19×Age</div>

Thus for most American boys between 3 and 16, you may safely assume that they started out life at 2 feet 7 inches and grew at the rate of two and a quarter inches per year.

This program probably misapplies *grap*; if you really want to perform least squares regressions on data, you should usually use a simple *awk* program like

```
awk '
        { x+=$1; x2+=$1*$1; y+=$2; xy+=$1*$2 }
END     { slope=(NR*xy-x*y)/(NR*x2-x*x); print (y-slope*x)/NR, slope }
' $*
```

(Be warned, though, that this program is not numerically robust.)

While we're on the subject of fitting straight lines to data, we'll redraw three graphs from J. W. Tukey's *Exploratory Data Analysis*. The file `usapop.d` records the population of the United States in millions at ten-year intervals.

```
1790    3.93
1800    5.31
1810    7.24
1820    9.64
1830   12.87
...
1950  150.7
```

Tukey's first two graphs indicate that the later population growth was linear while the early growth was exponential. The following *grap* program plots them as a pair, using `graph` commands to place internally unrelated graphs adjacent to one another.

```
graph Linear
        coord x 1785,1955 y 0,160
        label left "Population" "in Millions" left .2
        label right "Linear Scale," "Linear Fit"
        ticks bot off
        copy "usapop.d"
        define fit { 35 + 1.4*($1-1870) }
        line from 1850,fit(1850) to 1950,fit(1950)
graph Exponential with .Frame.n at Linear.Frame.s -(0,.05)
        coord x 1785,1955 y 3,160 log y
        label left "Population" "in Millions" left .2
        label right "Logarithmic Scale," "Exponential Fit"
        copy "usapop.d"
        define fit { exp(0.75 + .012*($1-1800)) }
        line from 1790,fit(1790) to 1920,fit(1920)
```

The statements defining each graph are indented for clarity. The second graph has the northern point of its frame 0.05 inch below the southern point of the frame of the first graph; the `with` clause is passed directly through to *pic* without being evaluated for macros or expressions. The names of both graphs begin with capital letters to conform to *pic* syntax for labels.
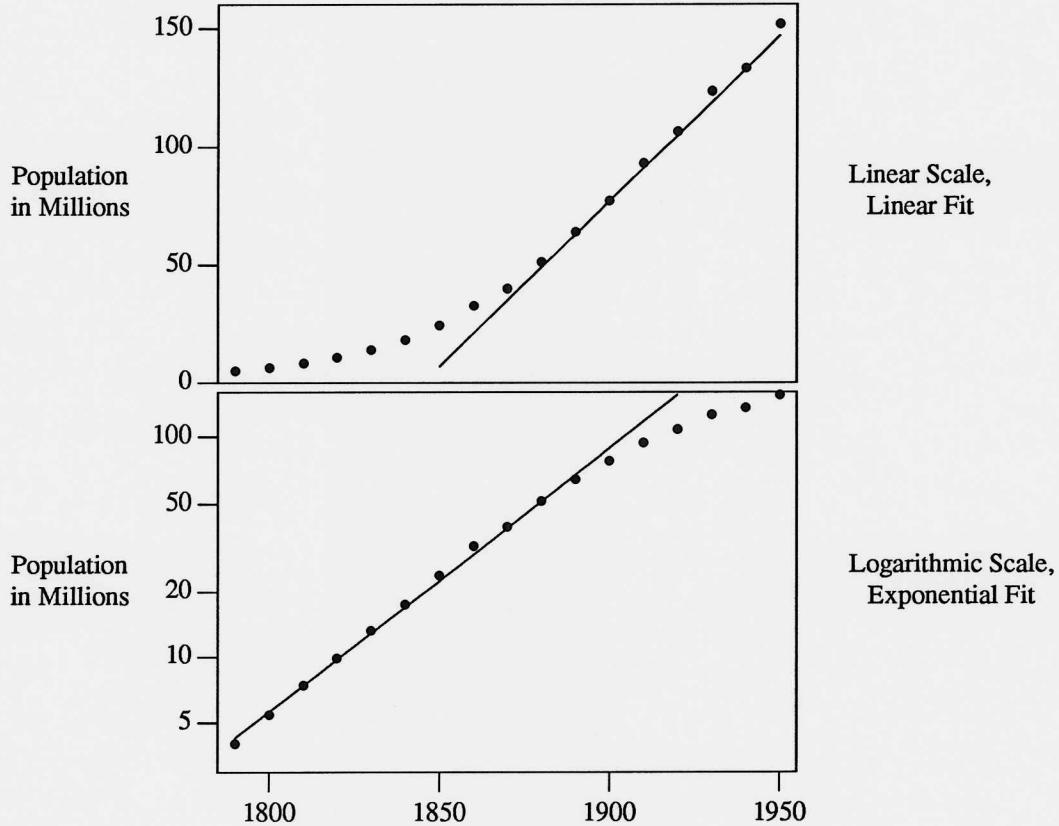

Polynomial functions lie between the linear and exponential functions; Tukey shows how a seventh-degree polynomial provides a better (and longer) fit to the early population growth.

```
label left "Population" "in Millions" left .2
label right "$x$ re-expressed as" "" \
        "$space 0 left ( {date - 1600} over 100 right ) sup 7$" left 1.2
define newx { exp(7*(log(($1-1600)/100))) }
ticks bot out at newx(1800) "1800", newx(1850) "1850",\
                newx(1900) "1900"
copy "usapop.d" thru {
   if $1 <= 1900 then { bullet at newx($1),$2 }
}
```

This program re-expresses the *x*-axis with *grap* arithmetic and uses an `if` statement to graph only part of the data file. It produces
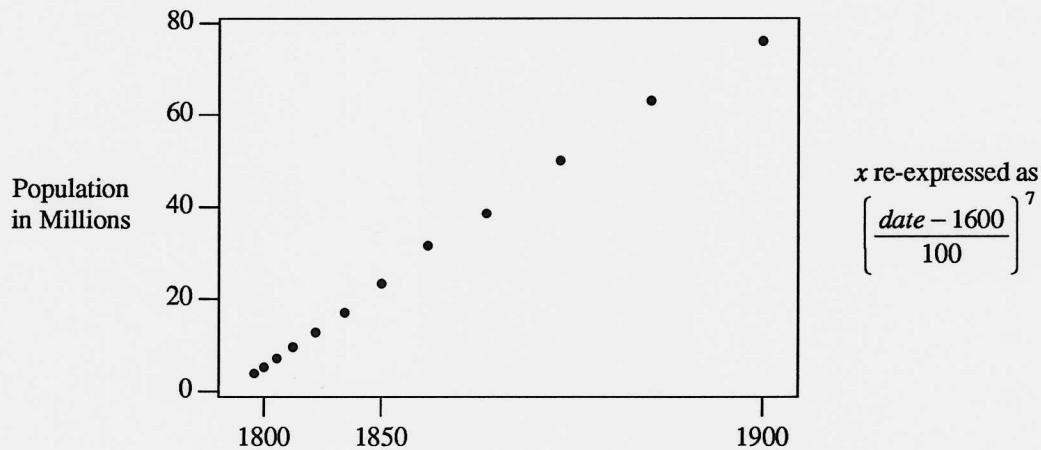

The *eqn* `space` `0` clause is necessary to keep *eqn* from adding extra space that would interfere with positions computed by *grap*; see Section 4.

The file `army.d` contains four related time series describing the United States Army.

```
40   16  .9   249   1
42  190  12  2867   1
43  521  36  6358  55
44  692  47  7144  71
45  772  62  7283  90
...
83   80   9   606  67
```

The first field is the year; the next four fields give the number of male officers, female officers, enlisted males and enlisted females, each in thousands. (Actually, there were no female enlisted personnel in the Army until 1943; the value 1 in 1940 and 1942 is just a placeholder, since *grap* has no mechanism for handling missing data.) The following *grap* program draws the four series with four different sets of `draw` and `next` commands.

```
coord x 38,85 y .8,10000 log y
label bot "U.S. Army Personnel"
label left "Thousands" left .3
draw of solid    # Officers Female
draw ef dashed   # Enlisted Female
draw om dotted   # Officers Male
draw em solid    # Enlisted Male
copy "army.d" thru {
        next of at $1,$3
        next ef at $1,$5
        next om at $1,$2
        next em at $1,$4
}
copy thru { "$1 $2" size -3 at 60,$3 } until "XXX"
Enlisted Men 1200
Male Officers 140
Enlisted Women 12
Female Officers 2.5
XXX
```

The program labels the lines by copying immediate data; the program is therefore shorter to write and easier to change. The delimiter string XXX in the until clause could be deleted in this graph: the .G2 line also denotes the end of data. Even though that string is enclosed in quotes, it may not contain spaces. The y-positions of the labels are the result of several iterations.
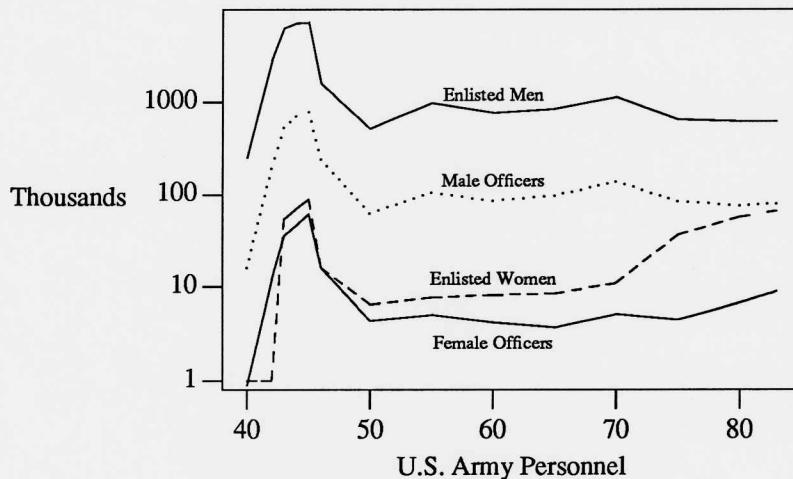

This data can tell many stories: the buildup during the Second World War is obvious, as is the exodus after the war; increases during Korea and Vietnam are also apparent. We will consider a different story: the ratio of enlisted men to the three other classes of personnel. There are several ways to plot this data (the most obvious graph uses three time series showing how the ratios change over time, and is left as an exercise for the reader).

We will instead construct a graph that gives little insight into this data, but illustrates a general method that is quite useful in conjunction with *grap*. The graph is a "scatterplot vector" that shows how one variable (the number of enlisted men) varies as a function of the other three. Breaking with tradition, we first show the final graphs, all of which have logarithmic scales.
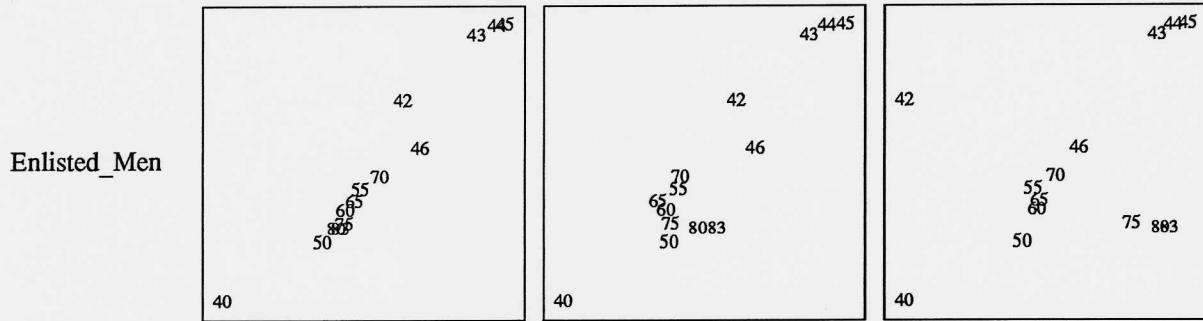

| Male_Officers | Female_Officers | Enlisted_Women |

The number of enlisted men is almost linearly related to the number of male officers, it is somewhat related to the number of female officers, and it varies widely as a function of the number of enlisted women.

Much more interesting than the graph itself is the method we used to produce it. We wrote a miniature "compiler" that accepts as its "source language" a description of a scatterplot vector and produces as "object code" a *grap* program to draw the graph. The source program for the above example is

```
file "army.d"
log x log y
symbol "\s-3$1\s+3"
y $4 Enlisted_Men
x $2 Male_Officers
x $3 Female_Officers
x $5 Enlisted_Women
```

The program lists several global attributes of the graph, the *y*-variable to be plotted, and as many *x*-variables as are desired; with each variable is its field in the file and a descriptive string. The language is "compiled" by the following *awk* program.

```
awk '
# Parse all commands
$1 == "file"     { fname = $2 }
$1 == "log"      { logtext = $0 }
$1 == "symbol"   { symtext = $2 }
$1 == "y"        { yfield = $2; ylabel = $3 }
$1 == "x"        { n++; xfield[n] = $2; xlabel[n] = $3 }
# Generate n graphs
END {    print ".G1"
         for (i = 1; i <= n; i++) {
                 if (s != "") print "#"
                 print "graph A" s
                 s = " with .Frame.w at A.Frame.e +(.1,0)"
                 print "frame ht " 5/n " wid " 5/n
                 print "label bot \"" xlabel[i] "\""
                 if (i == 1) print "label left \"" ylabel "\""
                 if (logtext != "") print "coord " logtext
                 print "ticks off"
                 print "copy " fname " thru { " symtext\
                       " at " xfield[i] "," yfield " }"
         }
         print ".G2"
}
' $1
```

Running this program on the above description produces the following output, which is typically piped directly to

grap.

```
graph A
frame ht 1.66667 wid 1.66667
label bot "Male_Officers"
label left "Enlisted_Men"
coord log x log y
ticks off
copy "army.d" thru { "\s-3$1\s+3" at $2,$4 }
#
graph A with .Frame.w at A.Frame.e +(.1,0)
frame ht 1.66667 wid 1.66667
label bot "Female_Officers"
coord log x log y
ticks off
copy "army.d" thru { "\s-3$1\s+3" at $3,$4 }
#
graph A with .Frame.w at A.Frame.e +(.1,0)
frame ht 1.66667 wid 1.66667
label bot "Enlisted_Women"
coord log x log y
ticks off
copy "army.d" thru { "\s-3$1\s+3" at $5,$4 }
```

The generated program uses the *pic* trick of re-using the same name (A) for several objects.

Although the program above is merely a toy, "minicompilers" can produce useful preprocessors for *grap*. The scatmat program, for instance, is a 90-line *awk* program that reads a simple input language and produces as output a *grap* program to produce a "scatterplot matrix", which is a handy graphical device for spotting pairwise interactions among several variables. If *grap* lacks a feature you desire, consider building a simple preprocessor to provide it. An alternative is to define macros for the task; which approach is best depends strongly on the job you wish to accomplish.

The next graph uses iterators to make a graph without reading data from a file. Rather, its "data" is a function of two variables that describes a derivative field and a function of one variable that describes one solution to the differential equation.

```
frame ht 2.5 wid 2.5
coord x 0,1 y 0,1
label bot "Direction field is $y sup prime = x sup 2 / y$"
label left "$y = sqrt {(2x sup 3 +1)/3}$" right .3
ticks left in 0 at 0,1
ticks bot in 0 at 0,1
len = .04
for tx from .01 to .91 by .1 do {
        for ty from .01 to .91 by .1 do {
                deriv = tx*tx/ty
                scale = len/sqrt(1+deriv*deriv)
                line from tx,ty to tx+scale,ty+scale*deriv
        }
}
draw solid
for tx = 0 to 1 by .05 do {
        next at tx, sqrt((2*tx*tx*tx+1)/3)
}
```

The left label uses *eqn* text between the $$ delimiters. The variable scale ensures that all lines in the direction field are the same length. The in clauses in the ticks statements specify that the ticks go in zero inches to avoid overprinting. The variables tx and ty are so named because x and y are reserved words for the coord statement.

$$y = \sqrt{(2x^3 + 1)/3}$$

Direction field is $y' = x^2/y$

Programmers familiar with floating point arithmetic may be surprised that the above graph is correct. Because of roundoff error, iteration "`from 0 to 1 by .05`" usually produces the values 0, .05, .10, ..., .95. *Grap* uses a "fuzzy test" in the `for` statement to avoid that problem, which may in turn introduce other problems. Such problems may be avoided by iterating over an integer range and incrementing a non-integer value within the loop.

Most of the data we have seen so far is inherently two (or more) dimensional. As an example of one-dimensional data, we will return to the populations of the fifty states, which is the third field in the file `states.d` introduced earlier; the file is sorted in increasing order of population. Our first graph takes the most space, but it also gives the most information.

```
frame ht 4 wid 5
label left "Rank in" "Population"
label bot "Population (Millions)"
label top "$log sub 2$ (Population)"
coord x .3,30 y 0,51 log x
define L { (2.0^$1)/1e6 "$1" }
ticks bot out at .5, 1, 2, 5, 10, 20
ticks left out from 10 to 50 by 10
ticks top out at L(19), L(20), L(21), L(22), L(23), L(24)
thisy = 50
copy "states.d" thru {
        "$1" size -4 at ($3/1e6, thisy)
        thisy = thisy-1
}
line dotted from 15.3,1 to .515,50
```

The L macro (for Label) with input parameter X evaluates to the number $2^X/1{,}000{,}000$ followed by the string "X" (the `ticks` command expects a number followed by a string label).

log$_2$ (Population)

Rank in Population

Population (Millions)

The dotted line is the least squares regression

$$\log_{10} Population = 7.214 - .03 \times Rank$$
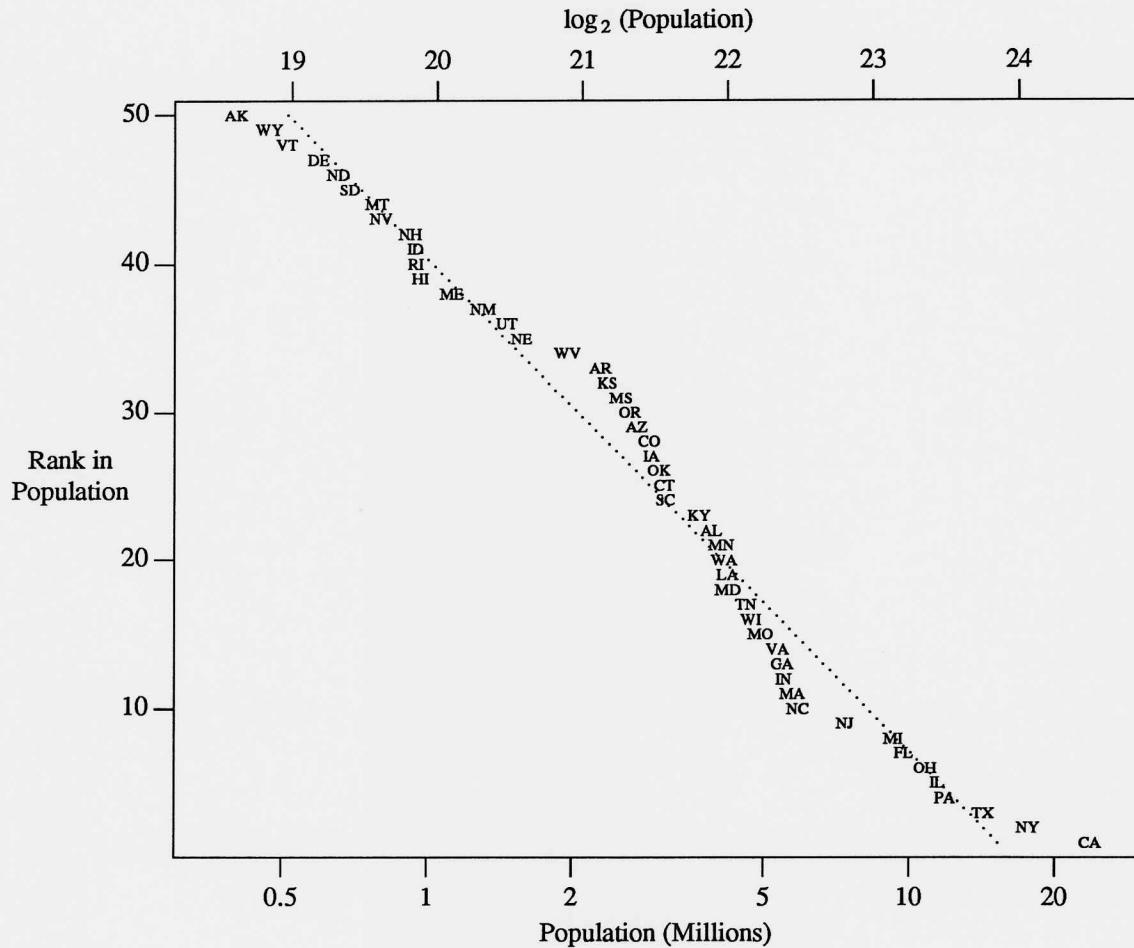

which gives 15.3 million as the population of the largest state and .515 million as the population of the smallest state. It says that population drops by a factor of two every ten states (compare the top and left scales). As sloppy as the exponential fit is, though, it is a much better fit to this data than a Zipf's Law curve is (drawing that curve is left as an exercise for the reader).

The next graph is a more standard representation of one-dimensional data.

```
frame invis ht .3 wid 5 bottom solid
label bot "Populations (in Millions) of the 50 States"
coord x .3,30 y 0, 1 log x
ticks bot out at .5, 1, 2, 5, 10, 20
ticks left off
copy "states.d" thru { vtick at ($3/1e6,.5) }
```

The markers were chosen to be vticks because they denote only an *x*-value.

Populations (in Millions) of the 50 States
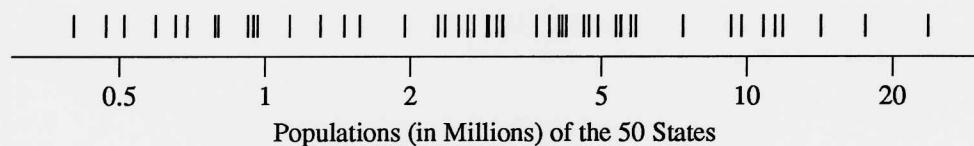

The next one-dimensional graph uses the state's name as its marker; to reduce overprinting the graph is "jittered" by using a random number as a *y*-value.

```
frame invis ht 1 wid 5 bottom solid
label bot "Populations (in Millions) of the 50 States"
coord x .3,30 y 0,1000 log x
ticks bot out at .5, 1, 2, 5, 10, 20
ticks left off
copy "states.d" thru { "$1" size -4 at ($3/1e6,100+900*rand()) }
```

The function rand() returns a pseudo-random real number chosen uniformly over the interval [0,1].

Populations (in Millions) of the 50 States
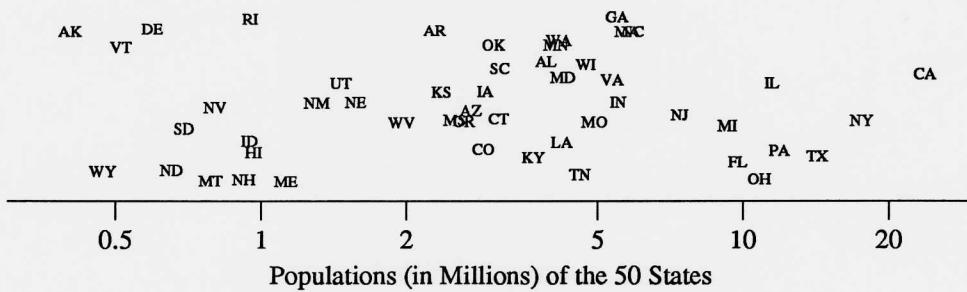

This graph is too cluttered; circles would have been a better choice as a plotting symbol (bullets, once again, would hide data).

Histograms are a standard way of presenting one-dimensional data in two-dimensional form. Our first step in building a histogram of the population data is the following *awk* program, which counts how many states are in each "bin" of a million people.

```
awk '
BEGIN    { bzs=0; bw=1e6 }  # bin zero start; bin width
         { count[int(($3-bzs)/bw)]++ }
END      { for (i in count) print i, count[i] }
' <states.d | sort -n >states2.d
```

The variable bzs tells where bin zero starts; although it is zero in this graph, it might be 95 in a histogram of human body temperatures in degrees Fahrenheit. The program produces the following output in states2.d:

```
0 12
1 5
2 7
3 5
4 7
...
23 1
```

There are 12 states with population between 0 and 999,999, 5 states with population between 1,000,000 and 1,999,999, and so on.

This *grap* program uses three line commands to plot each rectangle in the histogram.

```
frame invis bot solid
label bot "Populations (in Millions) of the 50 States"
label left "Number" "of" "States" left .3
ticks bot out from 0 to 25 by 5
coord x 0, 25 y 0, 13
copy "states2.d" thru {
        line from $1, 0 to $1, $2
        line from $1, $2 to $1+1, $2
        line from $1+1, $2 to $1+1 , 0
}
```

It produces
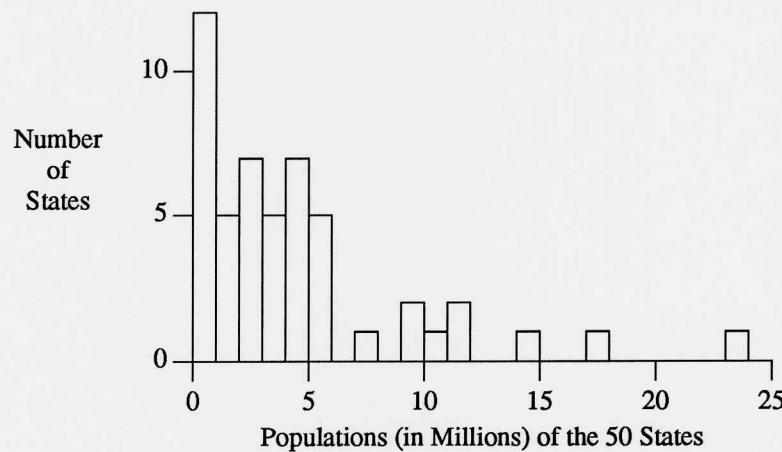

The same file can be plotted in a more attractive (and more useful) form by

```
frame invis bot solid left solid
label bot "Populations (in Millions) of the 50 States"
label left "Number" "of" "States" left .3
ticks bot out from 0 to 25 by 5
coord x 0, 25 y 0, 13
copy "states2.d" thru {
        line dotted from $1+.5, 0 to $1+.5, $2
        "\(bu" size +3 at $1+.5, $2
}
```

which produces one of Bill Cleveland's ''dot charts'' or ''lolliplots'':
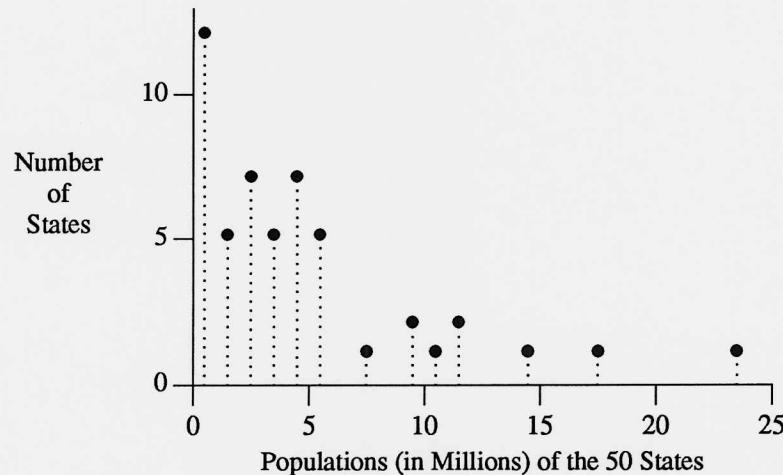

(We use \ (bu, the *troff* character for a bullet, rather than the built-in string to get a larger size.)

Other histograms are possible. The following *awk* program

```
awk '
BEGIN   { bzs=0; bw=1e6 }  # bin zero start; bin width
        { thisbin=int(($3-bzs)/bw); print $1, thisbin, count[thisbin]++ }
' <states.d >states3.d
```

produces the file `states3.d`

```
AK 0 0
WY 0 1
VT 0 2
DE 0 3
ND 0 4
...
CA 23 0
```

which lists the state's abbreviation, bin number, and height within the bin. The *grap* program

```
frame invis wid 4 ht 2.5 bot solid
ticks bot out from 0 to 25 by 5
ticks left off
label bot "Populations (in Millions) of the 50 States"
coord x 0,25 y 0,13
copy "states3.d" thru { "$1" size -4 at $2+.5, $3+.5 }
```

reads that file to make the following histogram, in which the state names are used to display the heights of the bins. In each bin, the states occur in increasing order of population from bottom to top.

```
HI

RI

ID

NH

NV

MT   IA   MO

SD   CO   WI

ND WV AZ AL TN NC

DE NE OR KY MD MA

VT UT MS SC LA IN

WY NM KS CT WA GA         FL      PA

AK ME AR OK MN VA     NJ    MI OH IL      TX       NY            CA
   ┌─────────┬─────────┬─────────┬─────────┬─────────┬─────────┐
   0         5        10        15        20        25
```

Populations (in Millions) of the 50 States
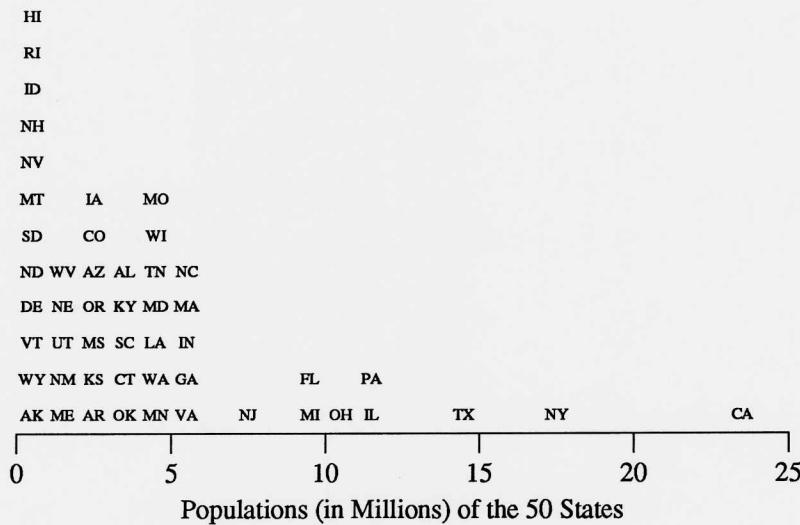

The next data set is a run-time profile of an early version of *grap*, created by compiling the program with the -p option and running `prof` after the program executed.

```
%time   cumsecs   #call   ms/call   name
 21.1     11.02   26834      0.41   _yylook
 11.2     16.89      30    195.60   _yyparse
  9.3     21.75                     __doprnt
  9.1     26.52                     _write
...
  0.0     52.19     170      0.00   _tickside
```

Although there were more than fifty procedures in the program, the top four time-hogs accounted for more than half of the run time. This file is difficult for *grap* to deal with: even though `if` statements would allow us to extract lines 2 through 11 of the file, we could not remove the leading _ from a routine name or access the last field in a record. We will therefore process it with the following *awk* program.

```
awk '
NR==2, NR==11 { print $1, substr($NF,2) }
' <prof1.d >prof2.d
```

The program produces

```
21.1 yylook
11.2 yyparse
9.3 _doprnt
9.1 write
5.9 input
...
2.0 nextchar
```

We could even use the *sh* statement to execute the *awk* program from within *grap*, which would make the latter entirely self-contained (see the reference manual for details).

We will display the data with this program.

```
ticks left off
cury = 0
barht = .7
copy "prof2.d" thru {
        line from 0, cury to $1, cury
        line from $1, cury to $1, cury-barht
        line from 0, cury-barht to $1, cury-barht
        "  $2" ljust at 0, cury-barht/2
        cury = cury-1
}
line from 0, 0 to 0, cury+1-barht
bars = -cury
frame invis ht bars/3 wid 3
```

Observe that the program knows nothing about the range of the data. It uses default ticks and a `frame` statement with a computed height to achieve total data independence.
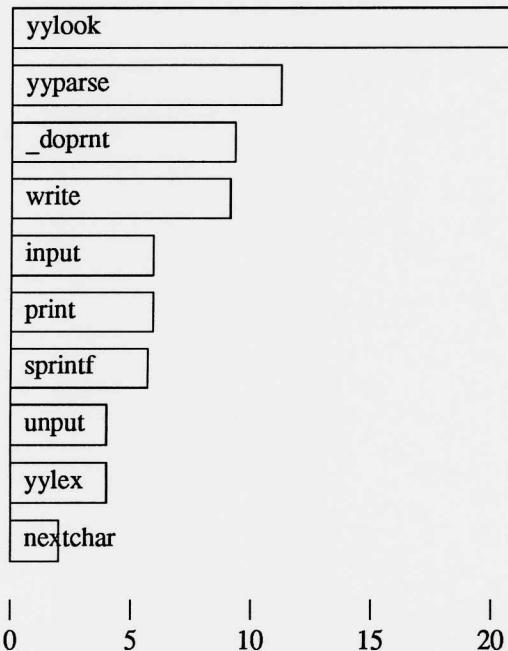

This bar chart highlights the fact that most of the time spent by *grap* is devoted to input and output.

    J. W. Tukey's box and whisker plots represent the median, quartiles, and extremes of a one-dimensional distribution. The following *grap* program defines a macro to draw a box plot, and then uses that shape to compare the distribution of heights of volcanoes with the distribution of heights of States of the Union.

```
frame invis ht 4 wid 3 bot solid
ticks off
coord x .5,3.5 y 0,25
define Ht { "- $1,000 -" size -3 at 2,$1 }
Ht(5); Ht(10); Ht(15); Ht(20)
"Highest Point" "in 50 States" at 1,23
"Heights of" "219 Volcanoes" at 3,23
"Feet" at 2,21.5; arrow from 2,22.5 to 2,24
define box { #(x, min, 25%, median, 75%, max, minname, maxname)
        xc = $1; xl = xc-boxwidth/2; xh = xc+boxwidth/2
        y1 = $2; y2 = $3; y3 = $4; y4 = $5; y5 = $6
        bullet at xc,y1
        "  $7" size -3 ljust at (xc,y1)
        line from (xc,y1) to (xc,y2)   # lo whisker
        line from (xl,y2) to (xh,y2)   # box bot
        line from (xl,y3) to (xh,y3)   # box mid
        line from (xl,y4) to (xh,y4)   # box top
        line from (xl,y2) to (xl,y4)   # box left
        line from (xh,y2) to (xh,y4)   # box right
        line from (xc,y4) to (xc,y5)   # hi whisker
        bullet at xc,y5
        "  $8" size -3 ljust at (xc,y5)
}
boxwidth = .3
box(1, .3, 2.0, 4.6, 11.2, 20.3, Florida, Alaska)
box(3, .2, 3.7, 6.5,  9.5, 19.9, Ilhanova, Guallatiri)
```

Boxes are one of many shapes used for the graphical representation of several quantities. If you use such shapes frequently then you should make a library file of their macros to copy into your *grap* programs. The above program produces

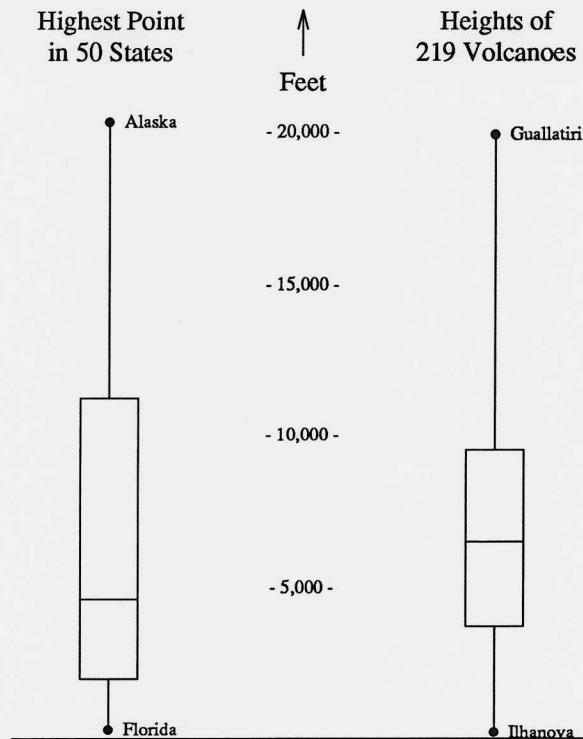

Even though the extreme heights are the same, state heights have a lower median and a greater spread.

Someday you may use *grap* to prepare overhead transparencies, only to find that everything comes out too small. The following program illustrates some ways to get larger graphs.

```
.ps 14
.vs 18
.G1 4
frame ht 2 wid 2
label left "Response" "Variable" left .5
label bot "Factor Variable"
line from 0,0 to 1,1
line dotted from .5,0 to .5,1
define blob X "\v'.1m'\(bu\v'-.1m'" X
blob at 0,.5; blob at .5,.5; blob at 1,.5
.G2
.ps
.vs
```

The `ps` and `vs` commands preceding the graph set the text size to 14 points and the vertical spacing to 18 points; the two quantities are reset by the commands following the `.G2`. Such size changes should be made outside the *grap* program, as mentioned earlier. The `4` following the `.G1` stretches the graph (including *grap*'s estimate of the accompanying text) to be four inches wide; it is an alternative to altering the `frame` command. The macro `blob` is a plotting symbol that is much larger than `bullet`; the different name ensures that later references to `bullet` are unaffected. The *troff* commands within the `blob` string move the character down one-tenth of an em to center its plotting position (determined experimentally) and then reset the vertical position. The program produces this trivial (but large) graph.
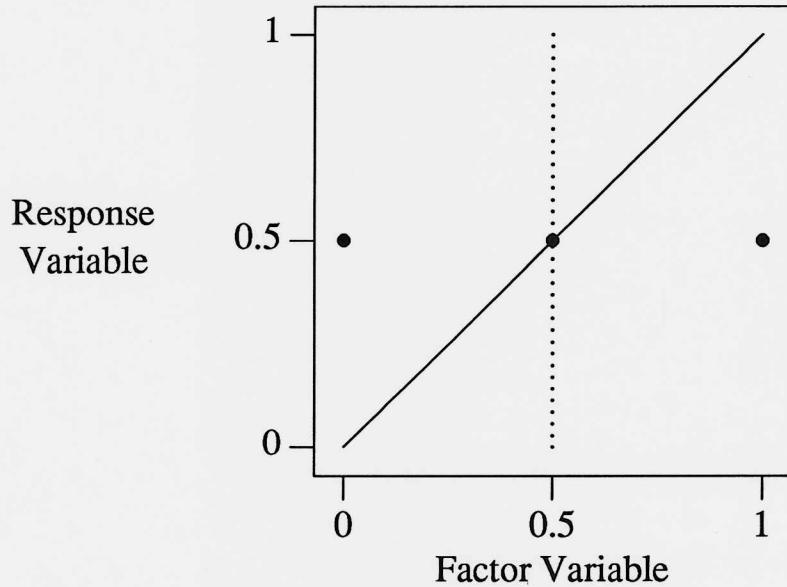

4. Using Grap

Following are a few day-to-day matters about using *grap*.

4.1. Errors

Grap attempts to pinpoint input errors; for example, the input

```
.G1
i = i + 1
```

results in this message on `stderr`:

```
grap: syntax error near line 1, file -
  context is
          i = i >>> + <<< 1
```

The error was noticed at the +. Unfortunately, pinpointing is not the same as explaining: the real error is that the variable i was not initialized.

The "words" x and y are reserved (for the coord statement); you will get an equally inexplicable syntax error message if you use them as variable names. (This design is bad, but not nearly so bad as having the log and exp functions use base 10.)

Grap tries to load a file of standard macro definitions (/usr/lib/grap.defines) for terms like bullet, plus, etc. It doesn't complain if that file isn't found, but if you later use one of these words, you'll get a syntax error message.

Certain constructs suggested by analogy to *pic* do not work. For example, .GS and .GE would have been nicer than .G1 and .G2, but they were already taken. The *pic* construct

```
.PS <file
```

has been superseded by *grap*'s copy command (which in turn has been retrofitted into *pic*).

4.2. *Troff* issues

You may use *troff* commands like .ps or .ft to change text sizes and fonts within a graph, or use balanced \s and \f commands within a string. Do not, however, add space (.sp) or change the line spacing (.vs, .ls) within a graph. Some defined terms like bullet contain embedded size changes; further qualifying them with *grap* size commands may not always work.

Because *grap* is built on top of *pic*, the following quote from the *pic* manual is relevant: "There is a subtle problem with complicated equations inside *pic* pictures — they come out wrong if *eqn* has to leave extra vertical space for the equation. If your equation involves more than subscripts and superscripts, you must add to the beginning of each such equation the extra information space 0". This feature was illustrated in the graph of the United States population in Section 3.

4.3. Alternatives

Besides *grap* and your local draftsperson, what other choices are there?

The S system [1] provides a host of tools for statistical analysis, but somewhat fewer tools than *grap* for producing document-quality graphs. S produces graphs on the screen of a DMD 5620 terminal much more quickly than *grap* (often in seconds rather than minutes), but it takes somewhat longer to learn (at least for us). If you expect to do a lot of interactive data analysis, then S is probably the right tool for you. S may be used to generate *pic* commands.

The standard UNIX program *graph* provides many of the basic features of *grap*, though with quite a bit less control over details, particularly text. It produces output only in the UNIX *plot*(5) language, which may be processed by a variety of filters for a variety of output devices.

The original UNIX typesetter graphics programs are *pic* and *ideal*; you may be able to do as well without using *grap* as an intermediary. In particular, *ideal* provides shading and clipping, which are useful in presentation-quality bar charts and the like, but are well beyond the capabilities of *pic*.

6. Reference Manual

In the following, *italic* terms are syntactic categories, `typewriter` terms are literals, parenthesized constructs are optional, and ... indicates repetition. In most cases, the order of statements, constructs and attributes is immaterial.

```
grap program:
        .G1 (width in inches)
        grap statement
        ...
        .G2
```

A width on the `.G1` line overrides the computed width, as in *pic*.

```
grap statement:
        frame | label | coord | ticks | grid | plot | line | circle | draw | new | next
        | graph | numberlist | copy | for | if | sh | pic | assignment | print
```

The `frame` statement defines the frame that surrounds the graph:

```
frame:
        frame (ht expr) (wid expr) ((side) linedesc) ...
side:
        top | bot | left | right
linedesc:
        solid | invis | dotted (expr) | dashed (expr)
```

Height and width default to 2 and 3 inches; sides default to solid. If *side* is omitted, the *linedesc* applies to the entire frame. The optional expressions after `dotted` and `dashed` change the spacing exactly as in *pic*.

The `label` statement places a label on a specified side:

```
label:
        label side strlist ... shift
shift:
        left | right | up | down expr ...
strlist:
        str ... (rjust | ljust | above | below) ... (size (±) expr) ...
str:
        "..."
```

Lists of text strings are stacked vertically. In any context, string lists may contain clauses to adjust the position or change the point size. Each clause applies to the string preceding it and all following strings. Labels may also have a `width` attribute, to override *grap*'s default computation.

Normally the coordinate system is defined by the data, with 7 percent extra on each side. (To change that to 5 percent, assign 0.05 to the *grap* variable `margin`, which is reset to 0.07 at each `.G1` statement.) The `coord` statement defines an overriding system:

```
coord:
        coord (name) (x expr,expr) (y expr,expr) (log x | log y | log log)
```

Coordinate systems can be named; ranges, logarithmic scaling, etc., are done separately for each.

The `ticks` statement places tick marks on one side of the frame:

ticks :
                    ticks *side* (in | out *(expr)*) *(shift)* *(tick-locations)*
tick-locations :
                        at *(name) expr (str)*, *expr (str)*, ...
                    | from *(name) expr* to *expr* (by *(op) expr) str*

If no ticks are specified, they will be provided automatically; ticks off suppresses automatic ticks. The optional expression after in or out specifies the length of the ticks in inches. The optional name refers to a coordinate system. If *str* contains format specifiers like %f or %g, they are interpreted as by printf. If no *str* is supplied, the tick labels will be the values of the expressions.

If the by clause is omitted, steps are of size 1. If the by expression is preceded by one of +, -, * or /, the step is scaled by that operator, e.g., *10 means that each step is 10 times the previous one.

The grid statement produces grid lines along (i.e., perpendicular to) the named side.

grid :
                    grid *side (linedesc) (shift) (tick-locations)*

Grids are labeled by the same mechanism as ticks. It is possible to draw grids without ticks by placing the phrase ticks off after the side name and before the iterator.

Plot statements place text at a point:

plot :
                    strlist at *point*
                    plot *expr (str)* at *point*
point :
                    (name) expr,expr

As in the label statement, the string list may contain position and size modifiers. The plot statement uses the optional format string as in C's printf statement — it may contain a %f or %g. The optional name refers to a coordinate system.

The line statement draws a line or arrow from here to there:

line :
                    (line | arrow) from *point* to *point (linedesc)*

The circle statement draws a circle:

circle :
                    circle at *point* (radius *expr*)

The radius is in inches; the default size is small.

The draw statement defines a sequence of lines:

draw :
                    draw *(name) linedesc (str)*

Subsequent data for the named sequence will be plotted as a line of the specified style, with the optional *str* plotted at each point. The next statement continues a sequence:

next :
                    next *(name)* at *point (linedesc)*

If a line description is specified, it overrides the default display mode for the line segment ending at *point*. The new statement starts a new sequence; it has the same format as the draw statement.

A line consisting of a set of numbers is treated as a family of points x, y_1, y_2, etc., to be plotted at the single x value.

numberlist :
                    number ...

If there is only one number it is treated as a y value, and x values of 1, 2, 3, ... are supplied automatically.

Grap provides arithmetic with the operators +, -, *, /, and ^. Variables may be assigned to; assignments are expressions. Built-in functions include `log`, `exp` (both base 10 — beware!), `int` (truncates towards zero), `sin`, `cos` (both use radians), `atan2(dy,dx)`, `sqrt`, `min` (two arguments only), `max` (ditto), and `rand()` (returns a real number random on [0,1)).

The `for` statement provides a modest looping facility:

for :
                    for *var* from *expr* to *expr* (by *(op)* *expr*) do { *anything* }

The string may contain internally balanced braces. Alternatively, any other character may appear immediately after the word `do`, and the string is terminated by the next occurrence of that character. The text *anything* (which may contain newlines) is repeated as *var* takes on values from *expr1* to *expr2*. As with tick iterators, the `by` clause is optional, and may proceed arithmetically or multiplicatively. In a `for` statement, the `from` may be replaced by "=".

The `if-then-else` statement provides conditional evaluation:

if :
                    if *expr* then { *anything* } else { *anything* }

The `else` clause is optional. Relational operators include ==, !=, >, >=, <, <=, !, ||, and &&. Strings may be compared with the operators == and !=.

It is possible to convert numeric expressions to formatted strings:

         sprintf(*"format"*, *expr*, *expr*, ...)

is equivalent to a quoted string in any context. Variants of %f and %g are the only sensible format conversions.

Grap provides the same macro processor that *pic* does:

         define *macro-name* { *anything* }

Subsequent occurrences of the macro name will be replaced by the string, with arguments of the form $*n* replaced by corresponding actual arguments. Macro definitions persist across `.G2` boundaries, as do values of variables.

The `copy` statement is somewhat overloaded:

         copy *"filename"*

includes the contents of the named file at that point;

         copy *"filename"* thru *macro-name*

copies the file through the macro; and

         copy thru *macro-name*

copies subsequent lines through the macro; each number or quoted string is treated as an argument. In each case, copying continues until end of file or the next `.G2`. The optional clause `until` *str* causes copying to terminate when a line whose first field is *str* occurs. In all cases, the macro can be specified inline rather than by name:

         copy thru { *macro body* }

The `sh` command passes text through to the UNIX shell.

sh :
              sh { *anything* }

The body of the command is scanned for macros. The built-in macro `pid` is a string consisting of the process identification number; it can be used to generate unique file names.

The `pic` command passes text through to *pic* with the "pic" removed; variables and macros are not evaluated. Lines beginning with a period (that are not numbers) are passed through literally, under the assumption that they are *troff* commands.

The `graph` statement

graph :
```
graph Picname (pic-text)
```

defines a new graph named *Picname*, resetting all coordinate systems. If any `graph` commands are used in a *grap* program, then the statement after the `.G1` must be a `graph` command. The *pic-text* can be used to position this graph relative to previous graphs by referring to their `Frames`, as in

```
graph First
 ...
graph Second with .Frame.w at First.Frame.e + (0.1,0)
```

Macros and expressions in *pic-text* are not evaluated. *Picname*s must begin with a capital letter to satisfy *pic* syntax.

The `print` statement

print :
```
print (expr | str)
```

writes on `stderr` as *grap* processes its input; it is sometimes useful for debugging.

Many reserved words have synonyms, such as `thru` for `through`, `tick` for `ticks`, and `bot` for `bottom`.

The # introduces a comment, which ends at the end of the line. Statements may be continued over several lines by preceding each newline with a backslash character. Multiple statements may appear on a single line separated by semicolons. *Grap* ignores any line that is entirely blank, including those processed by `copy thru` commands.

When *grap* is first executed it reads standard macro definitions from the file `/usr/lib/grap.defines`. The definitions include `bullet`, `plus`, `box`, `star`, `dot`, `times`, `htick`, `vtick`, `square`, and `delta`.
